

Session of Monday 27 October at 16.00-17.30 in aud A315.

1. Prove the ‘‘Gordon identity’’ on Vdh II.19:

$$\bar{u}(p + \frac{1}{2}\Delta, \lambda') [2m\gamma^{(\mu}p^{\nu)} - 2p^\mu p^\nu - p^{(\mu}i\sigma^{\nu)\alpha}\Delta_\alpha] u(p - \frac{1}{2}\Delta, \lambda) = 0$$

where $(\mu, \nu) \equiv \frac{1}{2}(\mu\nu + \nu\mu)$ denotes symmetrization.

2. (a) Consider qualitatively, using the uncertainty relation, the ordinary (x^0) time development of a $\gamma^*(\nu, Q^2) \rightarrow q(z\nu, \mathbf{p}_\perp)\bar{q}((1-z)\nu, -\mathbf{p}_\perp)$ fluctuation in DIS. The photon energy ν is large and the quark energy is $E_q = \sqrt{(z\nu)^2 + \mathbf{p}_\perp^2 + m_q^2}$. Estimate the life-time of the fluctuation from the energy difference between the γ^* and $q\bar{q}$ states. Use the transverse velocity $\mathbf{v}_\perp = \mathbf{p}_\perp/E_q$ to estimate the transverse distance to which the quark and antiquark can separate during the life-time of the fluctuation. How does this distance depend on the magnitudes of p_\perp , m_q and z ?
- (b) At the ep collider HERA electrons of 30 GeV collided with 800 GeV protons. Estimate the longitudinal distance, in the proton rest frame, between the $e\gamma^*e$ and $p\gamma^*X$ vertices for DIS events with $x_B = 0.001$.
3. Consider the QED amplitude $T_{+,\pm}(s, Q^2)$ describing $e(k, +)\mu(p, +) \rightarrow e(k, \pm)\mu(p', +)$, where \pm denote helicities, $s = (k + p)^2$ and $Q^2 = -(k - k')^2$. Take the high energy limit where k^+ , $p^- \rightarrow \infty$ at fixed Q^2 with $k_\perp = p_\perp = 0$, keeping the masses m_e and m_μ only where they contribute to the leading term. Define

$$T_{+,\pm}(s, Q^2) = -\frac{e^2}{Q^2} g_{\mu\nu} L_{+,\pm}^\mu(k, k') L_{+,\pm}^\nu(p, p') \quad (1)$$

where $L_{+,\pm}^\mu(k, k') = \bar{u}(k', \pm)\gamma^\mu u(k, +)$ and similarly for the muon vertex. Use the LF spinors given by (14) and by (21), (23) in the formula collection for the electron and muon vertices, respectively.

- (a) Show that the leading term of the non-flip vertices is $L_{+,+}^+(k, k') \simeq 2k^+$ and $L_{+,+}^-(p, p') \simeq 2p^-$ and hence find $T_{+,+}(s, Q^2)$ to leading order.
- (b) Show that $L_{+,-}^\mu(k, k') \simeq m_e\sqrt{2}(n^\mu e_+ \cdot q - e_+^\mu q^+)/k^+$. Find $T_{+,-}(s, Q^2)$ to leading order. Show that the ratio $T_{+,-}(s, Q^2)/T_{+,+}(s, Q^2) \propto 1/s^2$.
- (c) Include the contribution of the anomalous moment of the electron by adding a Pauli coupling $P_{+,\pm}^\mu(k, k') \equiv \bar{u}(k', \pm)i\sigma^{\mu\nu}(k - k')_\nu u(k, +)F_2(Q^2)/2m_e$, where $F_2(Q^2)$ is the Pauli form factor. Show that $T_{+,-}(s, Q^2)/T_{+,+}(s, Q^2)$ is independent of s due the Pauli contribution to $T_{+,-}$. Does this mean that the probability of a helicity flip for a physical electron actually does not decrease with the collision energy?
